ABSTRACT:

An audio-based guide arrangement is provided for guiding a user along a target path by the use of virtual audio beacons. The user's current location is sensed and compared to the target path. Sounds are fed to the user, for example through stereo headphones, to simulate one or more audio beacons appearing to be located in a direction at least approximating the direction of the target path onward from the user's current position. Preferably, each successive location of the audio beacon is determined by determining a segment onward from the user's current position of a piecewise linear approximation to the target path, and setting the apparent location of the beacon at or relative to the end of this segment.

ABSTRACT:

A compact beacon-detector type IFF system to be carried by individual soldiers. The system consists of a beacon and a special purpose detector. The beacon is a small, light-weight, battery powered device that is worn on the soldier's web gear. The detector consists of a small flashlight-like device that can be hand held or mounted on a weapon, similar to a rifle scope. The beacon's signal is not visible to those using existing night vision equipment nor is it otherwise exploitable by a potential adversary. The system achieves its covertness through the selection of the optical wavelength used by the beacon. Further signature reduction is achieved through the use of a Low Probability of Intercept ("LPI") spread spectrum waveform as the beacon output. This waveform utilizes a spreading code to encode the beacon output signal. Even if an enemy has a sensor capable of detecting the proper optical wavelength, it would not be able to detect or emulate the beacon's signal without prior knowledge of the specific spreading code used. The detector of the present invention is designed to despread the beacon output waveform, allowing the signal to be detected. This spread/despread code can be changed as frequently as required, so that capture of the beacon or detector would not be a serious risk to compromising the system.

TITLE: Limiting access to information corresponding to a context

Summary of Invention Paragraph:

[0006] Virtual beacons comprise a point in three dimensional space such as a geographic location with an associated URL. Virtual beacons are typically electronically created and maintained, such as by a computing system on the Web. Virtual beacons have advantages over corresponding physical beacons. Such advantages accrue to virtual beacons because of the limitations inherent in physical beacons discussed above. The point in three-dimensional space comprising a virtual beacon is typically associated with a physical object such as a building or other structure, a point of interest, or a sign such as an advertising billboard. A device can be enabled to respond to a virtual beacon. One such device enablement is WebSign.TM. (by Hewlett Packard, a corporation in Palo Alto, Calif.).

Summary of Invention Paragraph:

[0007] A virtual beacon enabled device can be pointed at the physical object, point of interest, or sign associated with the point in three-dimensional space. When so pointed, the device can detect the virtual beacon associated therewith and its associated URL. The device can then retrieve an associated Web page, as directed by the URL. This allows a user to obtain useful information relevant to the physical object, point of interest, or sign associated with the point in three-dimensional space. To be effective, a virtual beacon enabled device will respond to a virtual beacon and retrieve its associated URL when the geographic location (e.g., latitude and longitude) of the associated physical object, point of interest, or sign falls within a search window of the device. The search window can correspond to the device being within some maximum range of the virtual beacon. The virtual beacon will then transmit to the device the latitude and longitude and/or another geographic location identity to the device, as well as the associated URL.

Summary of Invention Paragraph:

[0008] There exist many different ways by which to establish a beacon's location. One method entails utilizing traditional surveying techniques to fix the location of an IAP device. Unfortunately, this method is quite time consuming and expensive. As such, traditional surveying techniques are typically limited to known landmarks or to locations of significance. It would be cost prohibitive to survey in each and every one of the multitudes of IAP devices. Another method entails using the Global Positioning System (GPS) to establish the locations of IAP devices. However, GPS generally requires a direct line-of-sight to several of the orbiting satellites. Consequently, GPS cannot be used to establish the locations of indoor IAP devices. Another commonly used technique involves cellular triangulation. Unfortunately, cellular triangulation has limited accuracy (e.g., 100 meters for standard cell sizes and less than 25 meters for microcells). Furthermore, cellular triangulation is susceptible to multi-pathing problems indoors.

Brief Description of Drawings Paragraph:

[0012] FIG. 1 shows a web navigation system that implements one embodiment of the present invention, wherein the system includes a virtual beacon creator, a virtual beacon server, and a virtual beacon receiver.

Brief Description of Drawings Paragraph:

[0013] FIG. 2 is a block diagram showing the structure of the virtual beacon creator of FIG. 1, according to one embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0014] FIG. 3 shows the user interface of the virtual beacon creator of FIG. 2 for receiving user inputs, according to one embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0015] FIG. 4 illustrates one exemplary virtual beacon created by the virtual beacon creator of FIG. 1-3, according to one embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0016] FIG. 5 shows the structure virtual beacon server of FIG. 1, according to one embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0017] FIG. 6A shows the structure of the virtual beacon receiver of FIG. 1, according to one embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0018] FIG. 6B depicts an exemplary display of a virtual beacon, according to one embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0019] FIG. 7 depicts the structure of the virtual beacon projector of FIG. 6A, according to one embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0021] FIG. 8B depicts a network with a mobile computing device and peripheral and a virtual beacon database, according to an embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0022] FIG. 9 depicts an exemplary implementation of a method for associating a geographic location with a URL using an intelligent virtual beacon, according to an embodiment of the present invention.

Brief Description of Drawings Paragraph:

[0023] FIGS. 10A-C depict exemplary applications for a virtual beacon for providing information corresponding to a point in three-dimensional space to a client device, according to an embodiment of the present invention.

Detail Description Paragraph:

[0034] FIG. 1 shows a web navigation system 40 that implements one embodiment of the present invention. The web navigation system 40 includes a virtual beacon creator 50, a virtual beacon server 60, and a virtual beacon receiver 70. A wireless network 42 is used for communications among the above mentioned systems 50, 60, and 70. In addition, a wired network can be used for communication between the virtual beacon creator 50 and the virtual beacon server 60, and/or between the systems 50, 60, and 70. Wireless network 42 is used to exemplify one network medium upon which embodiments of the present invention may be practiced. However, the present invention is not limited to use with wireless networks. Embodiments of the present invention are well suited to use with any network connection modality. As used herein, unless otherwise stated to the contrary the term "wireless" is used to exemplify other connection modalities, as well.

Detail Description Paragraph:

[0035] The virtual beacon creator 50 can also be referred to as a virtual link creator. The virtual beacon server can also be referred to as a virtual link server. In addition, the virtual beacon receiver 70 can be referred to as a virtual

link receiver or a receiver.

Detail Description Paragraph:

[0036] FIG. 1 also shows a physical location 45 and a web page 46 hosted in a content web server (not shown). The web page 46 can be accessed via the wireless network 42 by the virtual beacon receiver 70. This means that the virtual beacon receiver 70 has Internet access capability. The web page 46 is related to the physical location 45. This means that the physical location 45 is represented in the virtual world by the web page 46. Alternatively, the physical location 45 has two or more web pages and the web page 46 represents two or more physical locations. Web page 46 (and other Web pages) can be cached. Beacon rules can be executed locally (e.g., on a user's device). Beacon rules can be executed locally, in one embodiment, with a secured database and run with secured algorithms (e.g., processes).

Detail Description Paragraph:

[0037] In accordance with one embodiment of the present invention, the web navigation system 40 bridges the physical real world and the virtual world together such that easy, quick, and convenient web navigation is achieved with minimized physical effort for the bridging. The web navigation system 40 achieves this by allowing the web address of the web page 46 for the physical location 45 to be virtually posted at the physical location 45 without employing any physical object (e.g., a physical beacon, a display screen, or a poster) to post the web address at the physical location 45. This means that the web navigation system 40 provides a virtual beacon (or virtual link) (e.g., the virtual beacon 91 in FIG. 5) that functions to post, display, or broadcast the web address of the web page 46 at the physical location 45.

Detail Description Paragraph:

[0038] Hereinafter, the term "physical beacon" refers to an electronic device or module that stores a web address and can transmit or broadcast the stored web address. The term "virtual beacon" or "virtual link", however, does not refer to any physical object such as the physical object such as the physical beacon. Instead, this term refers to an electronic file that contains the web address. The electronic file, however, serves the similar function as the physical beacon. The virtual beacon or virtual link can also be referred to as a web-sign.

Detail Description Paragraph:

[0041] As will be described in more detail below, the virtual beacon creator 50 creates the virtual beacon 91 for the physical location 45. The virtual beacon 91 is essentially a location-based electronic file (e.g., the file 92 in FIG. 5). This means that the electronic file 92 contains the positional data of the physical location 45 and the web address of the web page 46. In addition, other data (e.g., access range, direction, name of the web address, time range during which the virtual beacon is active) may also be included in the electronic file 92 that forms the virtual beacon 91. The location-based electronic file 92 is then sent by the virtual beacon creator 50 to the virtual beacon server 60 via either the wireless network 42 or the wired network 43. Each of the networks 42 and 43 employs an open standard communication protocol (e.g., the Hyper Text Transport Protocol (http)) for communication. Thus, each of the networks 42-43 is an Internet network. In one embodiment, information can be passed via a private network, which can use a private protocol, in a similar manner.

Detail Description Paragraph:

[0042] The virtual beacon server 60 then sends the virtual beacon electronic file 92 to any external receiver system (e.g., the receiver system 70) via the wireless network 42 when the external receiver system is at a particular location and sends a request for all virtual beacon files that have positional data indicating locations that are near the location at which the receiver system is currently located. For example, when the receiver system 70 is near the physical location 45

and requests to receive all virtual beacon files that contain positional data indicating locations that are near the location at which the receiver system 70 is located, the virtual beacon server 60 will send the virtual beacon electronic file 92 to the receiver system 70. The receiver system 70 then uses the web address contained in the virtual beacon electronic file 92 to access the web page 46, thus allowing the web address of the web page 46 to be virtually posted at the physical location 45 without employing any physical object to host the web address at the physical location 45. This makes the virtual beacon 91 a virtual link or virtual beacon that is not physically located at the physical location 45. The web navigation system 40 will be described in more detail below, also in conjunction with FIGS. 2-8.

Detail Description Paragraph:

[0043] As can be seen from FIGS. 1 and 4, the virtual beacon creator 50 creates the virtual beacon 91 by creating the electronic file 92 (both shown in FIG. 5) for the physical location 45. As described above, the virtual beacon 91 is not a physical object, but rather a location-based electronic file (e.g., the electronic file 92) that contains data. The data contained in the virtual beacon electronic file 92 include a positional data of the physical location 45 (e.g., latitude="37.345" and longitude="-122.56"). An altitude can be added as well (e.g., altitude="123"). In addition, the data contained in the electronic file 92 also include an access range data (e.g., range=2000 feet), a tag or label data (e.g., <label>=the hospital). Moreover, other data may also be included. For example, the data in the electronic file 92 may include a directional data specifying the direction or orientation of the beacon projection of the virtual beacon 91, as well as time range data indicating the times during which the virtual beacon 91 is active. The beacon projection means the direction at which the virtual beacon electronic file 92 can be received by an external receiver system (e.g., the receiver system 70) at or near the location of the virtual beacon 91. These other data can be collectively referred to as control data, property data, or control information.

Detail Description Paragraph:

[0044] In one embodiment, the virtual beacon creator 50 of FIG. 1 can be implemented by a computer system with communication functions with external networks. In other embodiments, the virtual beacon creator 50 can be implemented by software, hardware, or firmware. FIG. 3 shows the structure of the virtual beacon creator 50, which will be described in more detail below.

Detail Description Paragraph:

[0045] In FIG. 2, the virtual beacon creator 50 includes an association module 62, a user interface 64, a wireless transceiver 66, a web gateway 68, a positioning module 72, and a computing element (e.g., processor) 99. The user interface 64 is used to interact with the user of the virtual beacon creator 50, and to receive user inputs 74-78 of data that will be used to form the virtual beacon electronic file 92. As can be seen from FIG. 3, the user inputs include a range data input 74, a position data input 75, a tag/label data input 76, a time data input 77, and a web address (e.g., URL) data input 78. In addition, the user interface 64 may also access a map data database 79. This database 79 is used when the position data input 75 is actually an address input (e.g., "3000 History Street, Palo Alto, Calif."). In this case, the user interface 64 accesses the database 79 to convert the address input into the positional data (e.g., latitude="12.345" and longitude="89.123"; an altitude can also be part of the positional data).

Detail Description Paragraph:

[0047] Referring back to FIG. 2, the association module 62 receives all the user inputs 74-78 from the user interface 64. The association module 62 then forms the electronic file 92 (FIG. 4) that represents the virtual beacon 91. The electronic file 92 contains (1) the positional data of the physical location 45 (FIG. 1) at which the virtual beacon 91 is created or specified and (2) the control data (e.g., the web address of the web page 46 (FIG. 2) associated with the physical location

45 (FIG. 2), the access range of the virtual beacon 91, and the tag/label of the web address, etc.). The association module 62 can be implemented using known technology.

Detail Description Paragraph:

[0048] The positioning module 72 is employed to provide the positional data of the current position of the creator 50. This allows the association module 62 to require no positional data input from the user interface 64 when creating a virtual beacon file. In this case, the user of the creator 50 only needs to indicate that the virtual beacon takes the current position of the creator 50. In one embodiment, the positioning module 72 is a Global Positioning System (GPS) receiver module. Alternatively, the positioning module 72 can be implemented using other known technology. For instance, position can be determined via a range and pair of angles relative to a user's position, such as by using angular positioning devices and/or range finding devices.

Detail Description Paragraph:

[0049] Referring to FIGS. 1, 2 and 4, the location-based electronic file 92 is then sent by the virtual beacon creator 50 to the virtual beacon server 60 via either the wireless network 42 or the wired network 43. Each of the networks 42 and 43 can employ an open standard communication protocol such as the HyperText Transport Protocol (HTTP) for communications, or a private protocol. Thus, each of the networks 42-43 is an Internet network or a private network. The virtual beacon electronic file 92 received by the server 60 from the creator 50 are in a format such as the Extensible Markup Language (XML). Alternatively, other known web data formats may be employed for the virtual beacon electronic file 92.

Detail Description Paragraph:

[0050] The transmission from the virtual beacon creator 50 is dependent on the connection of the creator 50 with the external server 60. If the creator 50 is connected to the wired network 43, then the web gateway 68 is used to transmit the electronic file 92 created by the creator 50. If the creator 50 is connected to the wireless network 42, then the electronic file 92 is transmitted by the wireless transceiver 66. If the creator 50 is connected to both networks 42-43, then the electronic file 92 can be sent by either network. The wireless transceiver 66 can be implemented using known technology and the web gateway 68 can be implemented using known technology.

Detail Description Paragraph:

[0051] Referring back to FIG. 1, when the virtual beacon server 60 receives the location-based electronic file 92 representing the virtual beacon 91 (both shown in FIG. 5) for the physical location 45, the server 60 stores the electronic file 92. When requested, the server 60 sends the electronic file 92 to the requesting receiver (e.g., the receiver 70). The server 60 sends the virtual beacon files it has stored either in the web format (e.g., XML format) or in the email format. Thus, the server 60 is basically a combination of a web server and an email server. The server 60 has a web address so that remote systems having web browsing capability can access the server 60. In addition, the server 60 also has an email address. The structure of the server 60 is shown in FIG. 5, which will be described in more detail below.

Detail Description Paragraph:

[0052] In FIG. 5, the server 60 includes a gateway 101, an email or other server 102, a web server 103, a file server 147, a virtual beacon store 104, and a filtering module 105. Alternatively, the server 60 can function without some of the above mentioned modules. For example, the server 60 may not have the filtering module 105 or the email module 102. The gateway 101 is used to interface the server 60 with the networks 42 and 43 (FIG. 2). Thus, the gateway 101 is also an Internet-enabled gateway. Gateway 101 can also be a proprietary protocol gateway.

Detail Description Paragraph:

[0053] The email or other server 102 is used to send virtual beacon electronic files (e.g., the file 92 of FIG. 4) to remote receivers (e.g., the receiver 70 of FIG. 2). The email or other server 102 has an email or other address and can send the virtual beacon files in e-mail or another format. The email or other server 102 can be implemented using known technology. The email or other server 102 is typically using to delivery the virtual beacon files stored in the store 104 to a remote receiver (e.g., the receiver 70 of FIG. 2) instantly (e.g., without waiting for the receiver to request such virtual beacons). The server 102 can also send the virtual beacon files stored in the store 104 to a remote receiver when the receiver requests such files. Any file transfer method known in the art can be used.

Detail Description Paragraph:

[0054] The web server 103 is used to delivery the virtual beacon files stored in the store 104 to a remote receiver (e.g., the receiver 70 of FIG. 2) when the receiver requests such files (e.g., on-demand delivery). The web server 103 also includes a web address so that external systems can access the web server 103 for the virtual beacon files stored in the store 104. The web server 103 can be implemented using known technology.

Detail Description Paragraph:

[0055] During operation, the gateway 101 receives external location-based virtual beacon files (e.g., the electronic file 92 of FIG. 5) from external virtual beacon creators (e.g., the creator 50 of FIG. 2). The gateway 101 then sends the file to the virtual beacon store 104 where the file is stored.

Detail Description Paragraph:

[0056] When the gateway 101 receives a request from an external receiver (e.g., receiver 70 of FIG. 2) for virtual beacon files with positional data indicating positions that are in the vicinity of the position of the requesting receiver, the gateway 101 will cause the email server 102, the web server 103, or the file server 104 to reply. Which one of the servers 102-103 should be engaged to reply depends on the request. If the request is an email request, then the email server 102 is engaged. If the request is a web request, the web server 103 is used. If the request is a file request, the file server 104 is used.

Detail Description Paragraph:

[0057] In addition, the email server 102 is also used to perform the instant delivery service of the virtual beacon files. In this case, the email server 102 needs to know the recipient's email address (e.g., subscription). In this case, as soon as the gateway 101 receives a new file for a new virtual beacon, the email server 102 checks to see if it needs to send the newly created virtual beacon to one or more of its existing subscribers.

Detail Description Paragraph:

[0058] The filtering module 105 is used to filter out the virtual beacon files that are not supposed to be sent out. The filtering module 105 does this by using the access range of the requesting receiver and the projection range (or access range) of a virtual beacon to determine if the virtual beacon file needs to be transferred. For example, if a virtual beacon file specifies an access range (e.g., a projection range) of 300 yards while the request from the requesting receiver (e.g., the receiver 70; client device 820; FIG. 8B) specifies a range of twenty miles as an area of interest, and if the virtual beacon specifies a location that is within twenty miles and 300 yards from the current position or location of the requesting receiver, then the virtual beacon file will be transferred to the requesting receiver without being filtering out by the filtering module 105. The filtering module 105 may also implement different filtering schemes. Alternatively, the server 60 does not include this module. Filtering module 105 may also be deployed upon the client (e.g., user) device.

Detail Description Paragraph:

[0059] Referring back to FIG. 1, the virtual beacon receiver 70 is employed to receive the virtual beacons (e.g., the virtual beacon 91 of FIG. 4) from the server 60. The receiver 70 is a portable or mobile electronic device with wireless (and/or wired) Internet access functionality. In one embodiment, the receiver 70 is a Personal Digital Assistant (PDA), or a personal organizer. In another embodiment, the receiver 70 is a palm-top computer or a mobile computer. Alternatively, the receiver 70 can be any kind of information appliance, or any kind of small portable handheld electronic device or appliance which has limited processing, storage, and display resources (e.g., a watch, a cellular phone, or a pager). The computational element 99 in the user device 70 can be a separate computing element or an element embedded within a computation array such as a field programmable gate array (FPGA).

Detail Description Paragraph:

[0060] The operation of the virtual beacon receiver 70 is as follows. When the virtual beacon receiver 70 (e.g., client device 820; FIG. 8B) is at a particular physical location (e.g., a bank, a convention center, a bus stop, or simply at a corner of a street in a town, a landmark, historical location, or point of interest, etc., or any other geographical location) and the user thereof acts to have all the virtual beacons located in the area of interest of the receiver 70, the virtual beacon receiver 70 accesses the virtual beacon server 60 via the wireless network 42.

Detail Description Paragraph:

[0061] For example, when the virtual beacon receiver 70 is at or near the physical location 45 and wants to know all the virtual beacons in the area of interest of receiver 70, for example, around the current location at which the receiver 70 is located or someplace of interest to the user of receiver 70, the virtual beacon receiver 70 sends a request to the virtual beacon server 60 and receives all the virtual beacon files that contain the positional data indicating positions that are within the area of interest specified by the receiver 70.

Detail Description Paragraph:

[0062] The area of interest specified by client receiver device 70 can, but does not have to be, a range surrounding the current location of the receiver device 70. In this way, a user of receiver 70 can take a "virtual tour" of an area of interest around a particular geographical location, via the virtual beacon files available from virtual beacon server 60 corresponding to that area of interest.

Detail Description Paragraph:

[0063] The area of interest is specified by the receiver 70 in its request to the virtual beacon server 60. For example, the receiver 70 can specify an area of interest of fifteen miles, twenty miles, or thirty miles, etc. Where the area of interest is set to fifteen miles, any virtual beacon with an access range located within the fifteen mile area of interest of the receiver 70 will be sent from the sender 60 to the receiver 70. Importantly, in one embodiment, this allows a user the ability to pre-cache virtual beacon files locally on board receiver 70 (e.g., client device 820; FIG. 8B) where the access range of the virtual beacons intersects the area of interest specified for the receiver 70.

Detail Description Paragraph:

[0064] In one embodiment, server 60 can be aware of the location of receiver 70. However, in another embodiment, server 60 remains aware of the location of receiver 70. Advantageously, the privacy of a user is promoted in one embodiment, because the virtual beacons transferred to the client receiver 70 do not imply a location of the user; rather only an interest in an area. The area of interest and access range will be described in more detail below, in conjunction with FIG. 6.

Detail Description Paragraph:

[0065] The receiver 70 then displays all the virtual beacons received from the server 60. FIG. 6B shows one example of the displayed virtual beacons of the receiver 70. The virtual beacon files sent from the server 60 to the receiver 70 are in the XML data format in one embodiment. In another embodiment, virtual beacons can comprise another data format. The receiver 70 can also have a local filtering element (e.g., filter 825R; FIG. 8A) to selectively display virtual beacons.

Detail Description Paragraph:

[0066] As described above, the wireless network 42 is a wireless Internet network that allows the virtual beacon receiver 70 to communicate with the virtual beacon server 60 using an open standard communication protocol (e.g., HTTP or an email protocol, etc.) or a private protocol. Thus in one embodiment, the communication between the server 60 and the receiver 70 can follow typical Internet, file, or email communication. Thus, server 60 has a web address, file transfer protocol (FTP) address, or email address and the receiver 70 includes a web browsing capability, file transfer capability, and/or email capability. The receiver 70 accesses the server 60 using a web browser and the web address of the server 60. If email is used for the communication, the receiver 70 accesses the server 60 using its email software and the email address of the server 60.

Detail Description Paragraph:

[0068] In addition, the receiver 70 also specifies, in the request, the virtual access range of the virtual beacons to be received. This effectively limits the range or distance that the receiver 70 can receive a location-based virtual beacon file. For instance, if a virtual beacon file specifies an access range that is beyond the specified area of interest of receiver 70, such as from the current location of the receiver 70, the receiver 70 will not receive that virtual beacon file from the server 60. If however the virtual beacon file specifies an access range that is within the specified area of interest of the receiver 70, such as from the current location of the receiver 70, the receiver 70 will receive that virtual beacon file from the server 60. In one embodiment, this characterizes one default operating mode.

Detail Description Paragraph:

[0069] Alternatively, the request does not specify the virtual access range of the virtual beacons to be received. In this case, the access range data is stored in the receiver 70 and the filtering process takes place within the receiver 70 before the receiver 70 displays the received virtual beacon files.

Detail Description Paragraph:

[0070] The concept of access range is introduced to limit the display (e.g., visualization) of data. Access range may also tend to economize on traffic between the server 60 and the receiver 70 along the network 42. As is known, physical beacons have physical constraints, which can effectively limit access range. While a system where users are not limited by the physical constraints is desirable, some constraints can still be useful. For example, without any restraint, a system could cause users to see a very large number of virtual beacons, which could have unwanted effects such as cognitive confusion and beacon display overload.

Detail Description Paragraph:

[0071] In the web navigation system 40, a virtual beacon is a virtual entity; thus a virtual access range constraint is desirable. Users can experience the virtual beacons only within their respective digital horizons. As used herein, a digital horizon is a set of all the virtual beacons that are "activated" as a result of the user being in their range. While range is the property of an individual virtual beacon, the digital horizon is the temporal and spatial property of an individual user.

Detail Description Paragraph:

[0072] FIG. 6A shows the structure of the virtual beacon receiver 70 depicted in FIG. 1. FIG. 6A shows that receiver 70 includes a positioning module 111, an orientation module 112, a wireless transceiver 113, a web browser 114, an email (and/or e.g., a file transfer) module 115, a kernel 116, and a virtual beacon projector 110. These modules are connected together via an internal bus 117.

Detail Description Paragraph:

[0075] The wireless transceiver 113 is used to send requests for virtual beacons to the remote server 60 (FIG. 1) and to receive virtual beacon electronic files from the server 60 via the network 42 (FIG. 1). The transceiver 113 can be implemented using any known communication technology and is network-specific. Thus the transceiver 113 will not be described in more detail.

Detail Description Paragraph:

[0077] The kernel 116 is used to communicate and control power management and other features of the hardware of the receiver 70. It also acts as an interface, abstracting the hardware from the other components. This is important as different hardware configuration could be used for different application. The other important functionality of the kernel 116 includes keeping the onboard cache refreshed. On the users demand, the kernel 116 queries the positioning module 111 for the current location, ambiguates it by truncating the trailing digits, and uses the data to queries the server 60 (FIG. 1). The response is stored in the internal database 133, associated with the virtual beacon projector 110.

Detail Description Paragraph:

[0078] The main function of the projector 110 is to display the received virtual beacon files. FIG. 6B shows one example of the display. Each virtual beacon is displayed with the location information with respect to the current location of the receiver 70. The structure of the projector 110 is shown in FIG. 7, which will be described in more detail below.

Detail Description Paragraph:

[0079] Referring to FIG. 7, the virtual beacon projector 110 includes a vectoring filter 131, a digital horizon module 132, a database 133, and a user interface 134. The user interface 134 is employed to allow the user of the receiver to communicate with the projector 110. For example, when the projector 110 displays a number of virtual beacons such as those shown in FIG. 4 and the user wants to access the web page of one of them, the user can do so by clicking on one of the listed hyperlinks. The user interface 134 also includes a display (not shown in FIG. 7). The user interface 134 can be implemented using known technology and will not be described in more detail below.

Detail Description Paragraph:

[0080] The digital horizon module 132 is used to restrict the virtual access range of the receiver 70 (FIGS. 1 and 6A). This limits the range or distance that the receiver 70 can receive a location-based virtual beacon file. As described above, the user should only be able to experience the virtual beacons in his digital horizon. We define a digital horizon as a set of all the virtual beacons that are "activated" as a result of the user being in their range. While range is the property of an individual virtual beacon, the digital horizon is the temporal and spatial property of an individual user. Thus, the range data is stored in the buffer 133 and the filtering process takes place within the receiver 70 before the receiver 70 displays the received virtual beacon files. Alternatively, the digital horizon module 132 is not included in the projector 110 and the filtering process takes place in the server 60 (FIG. 1).

Detail Description Paragraph:

[0081] The vectoring filter 131 is used to filter the virtual beacons that are in the direction pointed by the receiver 70 (FIGS. 1, 6A) and display them on the user interface 134. The kernel 116 of FIG. 7, in response to changes in the magnetometer

readings of the orientation module 112 of FIG. 6A, invokes the vectoring filter 131.

Detail Description Paragraph:

An Intelligent Virtual Beacon for Dynamically Providing Information Corresponding to a Point in Three-Dimensional Space

Detail Description Paragraph:

[0082] FIG. 8A depicts one exemplary deployment of an embodiment of the present invention between a virtual milieu (e.g., virtual world) 800V and a real milieu (e.g., real world) 800R from the standpoint of a user grounded within the real world 800R. In the present embodiment, a virtual beacon server 803 (which can embody the virtual beacon server 60 discussed in Section I above) comprises a virtual beacon database 802 and a filter 825V. Alternatively, in another embodiment, virtual beacon database 802 and filter 825V can be separate from the server 803, yet coupled thereto.

Detail Description Paragraph:

[0083] Server 803 receives location, time, direction, and related information (e.g., tilt) 855 about the user from the real world 800R. Through filter 825V, server 803 further receives contextual information 830V from the real world concerning the user. Contextual information 830V comprises, in one embodiment, information corresponding to contextual information 830R, which the user adds (or allows to be added) to a local (e.g., residing within real world 800R) database 841. However, the contextual information 830V received by filter 825V effectively comprises a version of contextual information 830R, which is sanitized (e.g., edited) to promote (e.g., safeguard, protect, etc.) the privacy of the user. In response to the information 855 and the context 830V, server 103 provides a set of virtual beacons 850 to real world 800R.

Detail Description Paragraph:

[0084] Information 826, which includes the location of the user as well as the corresponding time and direction, etc. are supplied to a filter 825R. Filters 825V and 825R can comprise an intelligent agent (e.g., intelligent agent 825; FIG. 8B). Such an intelligent agent can be deployed in either real world 800R, virtual world 800V, or both. Filter 825R receives contextual information 830R from local database 841. The user can interact with filter 825R, such as to control privacy settings or otherwise control filter 825R, via a user interface 820R. In one embodiment, the information 855 and sanitized contextual information 830R are supplied to virtual beacon server 803 by filter 825R. In one embodiment, virtual world 800V and real world 800R can be linked by a network (e.g., network 800; FIG. 8B). The agent can be deployed on a user device (e.g., device 820; FIG. 8B) or on a remote server. Filter 825R, local database 841, and user interface 820R can comprise components of a remote computing element.

Detail Description Paragraph:

[0085] FIG. 8B depicts a network 800 with a mobile computing device 820 (e.g., receiver 70; FIG. 1) and a virtual beacon database 802, according to an embodiment of the present invention. Virtual beacon database 802 functions as a repository of virtual beacons, which are programmed by a user interface (UI) 801. Virtual beacon server 803 connects virtual beacon database 802 to the Internet 810, such that the virtual beacons can be sent to serve intelligently. Any number of virtual beacon databases may be connected to the Internet 810 by virtual beacon server 803. Each virtual beacon database has its own UI 801 for programming. Any number of virtual beacon servers 803 may also comprise the server side of network 800. A virtual beacon 850 provided by virtual beacon server 803 functions by correlating a point in three-dimensional space with an associated URL. This virtual beacon 850 can be used in conjunction with device 820, enabled to detect the beacon.

Detail Description Paragraph:

[0087] Upon creation by UI programmer 801, virtual beacon 850 is programmed to correlate a point in three-dimensional space, such as a geographic location or an entity located at that location, with an associated URL. virtual beacon 850 is then stored within virtual beacon database 802 in a form wherein the URL is mapped to the location.

Detail Description Paragraph:

[0091] Client device 820 can provide, in one embodiment, its location to network 800 such that components of the network such as virtual beacon server 803 and intelligent agent 825 can be aware of the location of client device 820. In another embodiment, importantly, the network components remain unaware of the location of client device 820, advantageously helping to protect the privacy of a user of device 820. In the present embodiment, the client device 820 specifies to the network an area of interest, which can, but does not have to, correspond to the current location of the device 820.

Detail Description Paragraph:

[0092] Client device 820 can be loaded with information comprising a set 830 (e.g., to database 829). Information set 830 is loaded on client device 820 by its user. This allows users to decide how much or how little information to load, thus providing the users with the capability of selecting their own degree of privacy with information sharing. The information comprising set 830 can provide context and other information about the user by which server 803 makes virtual beacon 850 selectively available to the user of client device 820.

Detail Description Paragraph:

[0093] Information set 830 can comprise subsets including historical data 831, identity 832, preferences 833, security (e.g., security settings) 834, credentials 835, user capabilities 836, user interests 837, content 838, and cookies 840. Client device 820 selectively provides this information to network 800; thus components of the network such as virtual beacon server 803 and intelligent agent 825 can be aware of the information pertinent to client device 820 and its user. Client device 820 can be instructed to provide information such to network 800 automatically or by user action. Further, client device 820 can send user requests to network 800; thus components of the network such as virtual beacon server 803 and intelligent agent 825 can be aware of the information the user of client device 820 is seeking.

Detail Description Paragraph:

[0098] A virtual beacon provided by virtual beacon server 803 functions within network 800 as a virtual beacon that is electronically created and maintained by a computing system on the Web (e.g., Internet) 810. For instance, the virtual beacon can be electronically created and maintained by UI programmer 801. Thus, various characteristics can be conferred upon virtual beacon 850 by UI programmer 801. Such a virtual beacon can thus be provided with attributes, including dynamic ones, which physical beacons could not support. Such characteristics can include, but are not limited to, time sensitivity, directionality, dynamic flexibility, a defined area of coverage, a dynamic area of coverage (where the virtual beacon has such dynamic flexibility), mobility (e.g., the ability for the virtual beacon to move), sequentiality, and the ability to dynamically vary accessibility based on external criteria.

Detail Description Paragraph:

[0099] The dynamically flexible accessibility of a virtual beacon deployed within network 800 can be based on external criteria that include, but are not limited to, user criteria, user profile information, user interests, user capabilities, user security, and user ownership of particular content, credentials, and/or cookies. Any of these criteria may be combined in any manner so as to include complex sequential and non-sequential relationships. Thus, the dynamically flexible accessibility can be made sensitive to, or in one embodiment partially or wholly

dependent upon the information loaded into a particular client device 820, including information set 830.

Detail Description Paragraph:

[0100] Virtual beacon 850 correlates a point in three-dimensional space with an associated URL. Time sensitivity confers upon virtual beacon 850 the capability of comprising an intelligent, dynamic virtual beacon in four-dimensional space linked to a corresponding URL. With virtual beacon 850 configured with time sensitivity, client device 820 will only detect the beacon during a specific set time interval. For instance, a virtual beacon 850 associated with a particular store is only detectable by a user's device 820 during the time interval during which the store is open.

Detail Description Paragraph:

[0101] Conferred with the characteristic of directionality, virtual beacon 850 is detectable by client device 820 only when the device has or is deployed in a particular angular or directional aspect with respect to the point in three dimensional space corresponding to the virtual beacon. Continuing with the previous example, a virtual beacon 850 associated with a particular store is only detectable (e.g., receivable) by a user's device 820 only when the user is at an accessible part of the store, such as the storefront or another authorized access thereto.

Detail Description Paragraph:

[0102] Dynamic flexibility is conferred upon virtual beacon 850 by UI programmer 801. Thus, if time sensitivity, directionality, or other characteristics must be changed, virtual beacon 850 may simply be reset with the new time, directionality, or other characteristics. Continuing with the previous example of a virtual beacon 850 associated with a particular store, the store's operating hours may change, such as a seasonal adjustment wherein the store is open later in summer to take advantage of longer daylight hours. In this event, the time interval that the virtual beacon 850 is detectable by a device 820 is simply reset by UI programmer 801 to reflect the new store hours. The store may make open unused door or construct another on the side of the store. In this event, the direction from which the virtual beacon 850 is detectable by a device 820 is simply reset by UI programmer 801 to extend to the side housing the new entrance, as well as the storefront.

Detail Description Paragraph:

[0103] Area of coverage programming by UI programmer 801 renders virtual beacon 850 detectable by a device 820 only when the area of interest specified by device 820 resides within a defined three-dimensional space. In one embodiment, the access range of the virtual beacon can be set. For example, a certain virtual beacon 850 may be associated with a hotel. However, its area of coverage programming renders the virtual beacon 850 detectable only by devices 820 that are present within a certain large conference hall, such as to guide a conference participant to various exhibits, speaker stations, or the like.

Detail Description Paragraph:

[0104] Further, area of coverage programming can be set in one embodiment to correspond with user actions, such as physical actions taken with respect to client device 820. In one embodiment, this programming can be done locally upon device 820. Virtual beacons downloaded to device 820 can be displayed in response to the user actions. Importantly, in one embodiment, this allows a user the ability to pre-cache virtual beacon files locally on board client device 820, such as where the access range of the virtual beacons intersects the area of interest specified by the client device 820. Advantageously, the privacy of a user is promoted in one embodiment, because the virtual beacons transferred to the client device 820 do not imply a location of the user; rather only an interest in an area.

Detail Description Paragraph:

[0105] Device 820 can be programmed to display downloaded virtual beacons in response to its inclination and/or declination with respect to the ground plane upon which the user is standing, which can be detected and converted to corresponding data by tilt detector 824. Thus, if a user points the device 820 down (e.g., towards the ground), virtual beacon 850 that has been downloaded thereto is displayed to provide a URL with information about ground transportation, utilities such as rest rooms or other conveniences, or any other information coded to correspond to pointing device 820 downwards. Likewise, if a user points device 820 upwards (e.g., away from the ground), virtual beacon 850 that has been downloaded thereto is displayed to provide a URL with information about air transportation, rooftop restaurants, rooftop bars, or other rooftop service establishments, or any other information coded to correspond to pointing device 820 upwards.

Detail Description Paragraph:

[0106] In another embodiment, server 60 can be aware of the location of device 820. The information can similarly be provided by server 803 responsive to the user action. For instance, server 803 can be programmed to be responsive to the inclination and/or declination of device 820 with respect to the ground plane upon which the user is standing, which can be detected and converted to corresponding data by tilt detector 824. Thus, if a user points the device down (e.g., towards the ground), server 803 can responsively send a virtual beacon 850 that provides a URL with information about ground transportation, utilities such as rest rooms or other conveniences, or any other information coded to correspond to pointing device 820 downwards. Likewise, if a user points device 820 upwards (e.g., away from the ground), server 803 can responsively send a virtual beacon 850 that provides a URL with information about air transportation, rooftop restaurants, rooftop bars, or other rooftop service establishments, or any other information coded to correspond to pointing device 820 upwards.

Detail Description Paragraph:

[0107] Conferred with the characteristic of mobility (e.g., motion), virtual beacon 850 can move within three-dimensional space. This feature can be useful for an application such as guiding users around and through the particular three-dimensional space through which virtual beacon 850 is moving by varying the region that client device 820 detects it. Thus, a user may be guided through a museum. Further, as users move following the moving beacon 850, they can be provided with information specific to each region of the three-dimensional space to which they are guided by linking with their device 820 to a particular URL corresponding to each region.

Detail Description Paragraph:

[0108] Continuing with the previous example of a moving virtual beacon 850 associated with a museum, each URL can describe what is displayed within the corresponding region, such as artifacts, works of art, or the like. Textual beacons can be displayed as well as a graphical views, including graphics of any format (e.g., JPG and MPEG files) and audio files. Upon visiting a certain landmark or point of interest, a user can be guided by a moving virtual beacon 850 to, for example, the next landmark to visit within a historical area. Upon taking in a particular scene or view at one observation point in a scenic or historically or otherwise significant area, a user can be guided using a device 820 to the next observation point, or to the direction of the next view from the one they are at. Further, a virtual beacon 850 conferred with motion can effectuate a virtual game based on a user finding the virtual beacon using their device 820.

Detail Description Paragraph:

[0109] Where a virtual beacon 850 is conferred with dynamic flexibility, it can further be conferred with a dynamic area of coverage, based upon another parameter such as time and/or criteria corresponding to information set 830 such as identity, interests, etc. Where the area of coverage of virtual beacon 850 changes based upon time, a device sensitive to the beacon can guide its users to the place they are to

be at a certain time. An event can comprise more than one stage, each stage held or occurring in a different location. Users attending the event can be guided to the right place at the right time using their beacon-sensitive devices 820, by means of the virtual beacon 850.

Detail Description Paragraph:

[0110] A wedding exemplifies such an event. The wedding's ceremony may be held in a certain church, to which ceremony invitees are guided by virtual beacon 850. Upon completion of the ceremony, the wedding party moves from the church to a certain reception hall, to which reception invitees are guided by the same virtual beacon 850, conferred with a dynamic area of coverage. If an invitee to both the ceremony and the reception shows up at the church late, e.g., after the wedding party has departed the church to the reception hall, the virtual beacon 850, conferred with a dynamic area of coverage, can link the user to two associated URLs, one which provides a link to a map to the reception hall, and another for example, providing information about the church, perhaps historically interesting information; perhaps religious information, times of services, and the like. Even this latter information can be rendered with temporal significance in one embodiment. For instance, if it is temporally close to the winter holiday season, graphical information such as a JPEG file of the church can be sent depicting the church set in a snowy background, perhaps garlanded & wreathed. If temporally it is spring, summer, or autumn however, the church can be shown with seasonally or other temporally significant graphics.

Detail Description Paragraph:

[0111] In one embodiment, a virtual beacon 850 can be downloaded at any time. However, based on context (and other facets gleaned from information set 830), the virtual beacon may only be accessed (e.g., receivable and displayable by) by device 820 at a certain time prescribed by the context. In one embodiment, this access restriction is effectuated by intelligent agent 825, based on context information (e.g., context 830R; FIG. 8A) used by the intelligent agent.

Detail Description Paragraph:

[0112] Besides temporally dynamic, the area of coverage of a virtual beacon 850 can be dynamic based on other criteria. Continuing with the instant wedding example, certain users may be invited to the reception, but perhaps not to the ceremony. Virtual beacon 850 can be programmed for dynamic area of coverage based upon the identities of the wedding invitees. Arriving at the church during the ceremony, the virtual beacon 850, conferred with a dynamic area of coverage, can link the user who is invited only to the reception to the two associated URLs discussed above, for example. One provides a link to a map and directions to the reception hall and the time that the reception is to begin. The other for example provides the information about the church. One user may be a member of the wedding party, such as the "best man." The link received by that user can direct him to a particular door behind the church to dress in the ceremonial attire and attend the rehearsal. Based on context, this link would only be provided to the best man, and would not be provided to anyone else.

Detail Description Paragraph:

[0113] Conferred with the characteristic of sequentiality, a certain virtual beacon 850 can be detected only after another (e.g., one or more) defined beacon has been acquired, or other sequential criteria are met. An example of a sequentially dynamic virtual beacon is an event such as a fair at which a virtual beacon is used inside the fairgrounds, such as to identify a particular exhibit, show, or attraction. However, the virtual beacons identifying the exhibit, show, or attraction therein are not detectable by a user device 820 until that device has first acquired a virtual beacon 850 corresponding to admission. Thus, a user must be admitted to the fair before acquiring the virtual beacons therein. Sequentiality allows a user to detect event occurrences in a logical fashion, wherein the event is dependent upon the occurrence of other events. In this case, a user's device 820

can only detect a virtual beacon 850 associated with one event or situation after a particular other event, set of events, sequence of events, or any combination thereof, as programmed by UI programmer 801, has occurred, such as a certain virtual beacon is detectable by a client device only after the client device has received a particular email from the associated location.

Detail Description Paragraph:

[0114] For example, a user may only detect a virtual beacon 850 associated with an approaching service plaza within a toll road and within the client device search window, upon passing a certain tollbooth. Another user may only detect a virtual beacon 850 associated with a certain courtesy kiosk after visiting a certain number of stores in a shopping mall. Another example is that of a virtual beacon 850 associated with a ski resort: its associated virtual beacon 850 is only detectable when the resort is open and the road by which it is accessed is clear.

Detail Description Paragraph:

[0115] A virtual beacon 850 can also be conferred with a characteristic corresponding to the physical accessibility to the point in three-dimensional space corresponding to the beacon, to a particular user. For instance, a certain virtual beacon may be associated with a filling station wherein the station is proximate to but not accessible from a toll road. Thus, the device 820 of user driving on the toll road would not be able to see (e.g., display) the virtual beacon associated with the inaccessible filling station, although the user may be passing quite close to the station. As the access range of the virtual beacon is within the area of interest specified by the client device, the virtual beacon is received, in one embodiment, however, it is filtered, so as not to be displayed. Although the access range of the virtual beacon intersects with the area of interest specified by the device 820, the virtual beacon is not displayed. Advantageously, the virtual beacon thus does not confuse the user, who cannot presently access the location associated with it.

Detail Description Paragraph:

[0116] Likewise, another filling station may be located within a service plaza on the toll road and have its own associated virtual beacon. The virtual beacon associated with the filling station in the toll road service plaza would be detectable by a user's device 820 where the user is approaching the vicinity of the service plaza. However, that virtual beacon would not be detectable by a user who is not on the toll road, despite the fact that they may be quite close by, such as driving on a frontage road adjacent to the toll road, but inaccessible to it.

Detail Description Paragraph:

[0117] A virtual beacon 850 can be conferred with the ability to be detected based upon user criteria. For instance, the virtual beacon can be programmed to be detectable based on a particular user criterion, or upon any combination of user criteria, user profile information, and/or characteristics, such as within user profile 840 or information set 830. As discussed above, such criteria can comprise physical information about the user such as age, height, weight, gender, etc., interests 837, previously acquired information or credentials, cookies, education level, passed on permissions, and similar information. Characteristics of client device 820 such as the device's authentication, display, and selected I/O and other capabilities can also comprise such user criteria.

Detail Description Paragraph:

[0118] Any of the characteristics discussed above: time, directionality, area of coverage, motion, dynamic area of coverage, sequentiality, physical accessibility, and user criteria, can be combined in any manner including simple and complex sequential and non-sequential relationships to confer corresponding attributes to a virtual beacon 850. For instance, continuing with the toll road and filling station examples above, a physical accessibility attribute of a virtual beacon 850 may comprise a user having engaged in a sequence of first paying a toll and then

driving within the area of coverage of the toll road service plaza filling station before the virtual beacon 850 associated with the toll road service plaza filling station becomes detectable by the user's device 820. Further, the virtual beacon 850 may only be detectable during hours the filling station is open. Through programming with these characteristics and their various combinations, virtual beacons can acquire a significant degree of intelligence of operation.

Detail Description Paragraph:

[0119] An intelligent agent 825 can be associated with a collection of virtual beacons 850 and can be deployed on either the virtual beacon server 803 side or the client 820 side of Internet 810. The intelligent agent 825 can detect that a certain client device 820 is accessing virtual beacons 850 associated with groups of locations (e.g., points in three-dimensional space), attempt to ascertain a correlation between the members of this group of locations, and responsively enable other virtual beacons 850 that it infers may be of interest to the user of client device 820, and that fall within the client's search window, as described above in Section I. Further, users of a client device 820 can utilize intelligent agent 825 to have a group of associated locations correlated by the users, themselves activate their associated virtual beacons 850 in response to a request transmitted by their device 820.

Detail Description Paragraph:

[0121] For instance, an intelligent agent 825 associated with a collection of virtual beacons 850 can detect that a user is accessing certain of the virtual beacons 850 belonging to the group, such as that a user is visiting all or some of the major wineries in a particular area. Upon detecting this, intelligent agent 825 can enable (e.g., activate) virtual beacons 850 associated with smaller and/or less known wineries in that area (e.g., that fall within the client's search window, as described above in Section I). A user can utilize the intelligent agent 825 to request activation of all virtual beacons within the client's search window that match a certain criterion or group of criteria, such as a particular purchase criterion. For example, the user requests the intelligent agent 825 to activate the virtual beacons 850 associated with all open stores within the search window that have a particular product currently available. Criteria can be added; for instance, request the intelligent agent 825 to activate the virtual beacons 850 associated with all open stores within the search window that have a particular product currently available, on sale, or below a certain price.

Detail Description Paragraph:

[0122] The dynamic and intelligent character of virtual beacons 850 allow the provision of timely and useful information, without superfluity, to users of enabled devices 820. Correlations of events are thus enabled by network 800. For instance, upon a change in weather, such as an unexpected rainstorm, virtual beacons 850 associated with local shops affected by the weather are enabled to advertise the sale of items useful in that weather milieu, such as umbrellas.

Detail Description Paragraph:

[0123] In one embodiment, a virtual beacon expires, e.g., is deactivated upon the occurrence of some associated, pre-programmed condition, such as upon a client device visiting and departing from the actual geographical location to which the virtual beacon is associated, an associated store closes, weather clears, an event is over, etc. This can advantageously save computing and network resources, as well as preventing now superfluous or temporarily erroneous information from presentation to an enabled client device and any possible associated nuisance.

Detail Description Paragraph:

[0124] For instance, expiring, e.g., deactivating, a virtual beacon at night for a landmark or attraction that is only open during daylight hours prevents the virtual beacon from mis-attracting a user of an activated client device to the now-closed place. This feature is also useful for applying virtual beacons as a tour guide or

route marker. For example, for a tourist user who only wants to visit a monument, landmark, etc. once, the virtual beacon can expire for that user's client device upon departing from the vicinity of the location.

Detail Description Paragraph:

[0125] Virtual beacons 850 can also be made available upon subscription, evinced for example by a credential or cookie placed upon the device 820 in return for paying a subscription fee. Subscription type virtual beacons 850 can provide access to pay-for-view type URLs or other services, tour guide services, such as by using a motion-enabled virtual beacon, premium type services at a location, and other services.

Detail Description Paragraph:

[0126] In one embodiment, virtual beacons 850 effectuate virtual tours of a location outside of the user's current location. In such a virtual tour, a user device 820 provides context via intelligent agent 825 corresponding to a desire, interest, whim, or the like to visit another (e.g., remote) location, at some future time for instance. Responsively, virtual beacons 850 corresponding to the location and/or to the prospective time (e.g., season) of the visit are sent to device 820.

Detail Description Paragraph:

[0127] Conferred with any of the characteristics discussed above: time, directionality, area of coverage, motion, dynamic area of coverage, sequentiality, physical accessibility, and user criteria, and any simple or complex sequential or non-sequential combination of these characteristics, virtual beacon 850 functions to intelligently dynamically provide information corresponding to a point in three-dimensional space to a user of a device 820 sensitive to the virtual beacon.

Detail Description Paragraph:

[0128] FIG. 9 is a flowchart of a process 900 for programming a virtual beacon. Process 900 begins with a step 901, wherein a request is received to correlate a point in three-dimensional (3-D) space with a certain URL, e.g., to create a virtual beacon for that point with the specified URL.

Detail Description Paragraph:

[0129] In step 902, the requested properties for the virtual beacon are ascertained by an entity receiving the request. Such an entity can control a user interface programming tool (e.g., UI programmer 801; FIG. 8) for configuring a virtual beacon.

Detail Description Paragraph:

[0130] In step 903, it is determined whether the virtual beacon is to be dynamic. If so, then in step 904, an intelligent and dynamic virtual beacon is configured according to the ascertained requested properties.

Detail Description Paragraph:

[0132] If it is determined that the virtual beacon is to be a simple static (e.g., non-dynamic) virtual beacon, then in step 905, a static virtual beacon is configured, upon which process 900 can be complete.

Detail Description Paragraph:

[0133] In step 906, it is determined whether conditions specified by programming the virtual beacon have changed. If so, then in step 907, the virtual beacon is modified accordingly, such as by re-programming.

Detail Description Paragraph:

[0134] For example, for a virtual beacon associated with a point in three-dimensional space corresponding to a certain store, when the scheduled time of day at which the store closes is reached, the virtual beacon is deactivated. The next

day, when the scheduled time of day at which the store opens is reached, the virtual beacon is reactivated.

Detail Description Paragraph:

[0135] In one embodiment, a virtual beacon expires, e.g., is deactivated upon the occurrence of some associated, pre-programmed condition, such as upon a client device visiting and departing from the actual geographical location to which the virtual beacon is associated. This can advantageously save computing and network resources, as well as preventing now superfluous information from presentation to a client device. A user device (e.g., device 820; FIG. 8B) can also be pre-programmed to look for activation and reactivation of such a virtual beacon.

Detail Description Paragraph:

[0136] Upon execution of step 907, or if it is determined in step 906 that the conditions specified by programming the virtual beacon have not changed, then process 900 loops back to repeat step 906.

Detail Description Paragraph:

[0138] FIGS. 10A, 10B, and 10C depict useful exemplary applications of virtual beacons. FIG. 10A depicts an exemplary "Shop at this Store" store having an associated virtual beacon 1000. Virtual beacon 1000 links the store (e.g., the point in three-dimensional space corresponding to the store's geographical location) to an exemplary corresponding URL, such as "www.shopatthisstore.com". The store's geographical location comprises latitude, longitude, and elevation. Elevation can be given if relevant, or it can be implied from the latitude and longitude, such as by reference to corresponding contour maps. Where given, it can be expressed in elevation with respect to sea level or stated to correspond to a certain floor, such as for a store located in a multi-story building.

Detail Description Paragraph:

[0139] Virtual beacon 1000 comprises a set of tags 1050 to include the latitude, longitude (and elevation, if relevant), and the associated URL. The associated URL will be visible (e.g., detectable) by an enabled client device (e.g., device 820; FIG. 8) if the latitude and longitude (e.g., Lat/Lon) fall within the client's search window, as described above in Section I, and the criteria defined by the tags are met. In the present exemplary implementation, the criteria defined by the tags are as follows:

Detail Description Paragraph:

[0140] Time: the virtual beacon is only visible during hours the store is open

Detail Description Paragraph:

[0141] Area of coverage: the virtual beacon is only visible within one tenth kilometer of the store's Lat/Lon

Detail Description Paragraph:

[0142] Directionality: the virtual beacon is only visible from the front of the store

Detail Description Paragraph:

[0144] Physical Accessibility: the virtual beacon is not visible from an adjacent toll road (e.g., because the store is inaccessible therefrom)

Detail Description Paragraph:

[0145] User Criteria: the virtual beacon is only visible to an adult's device

Detail Description Paragraph:

[0149] Similarly, where a device 820 contains context information, such as that the user thereof has a special interest or hobby, virtual beacons 850 can be provided to the device based upon such context information. For example, if interests 837

(FIG. 8B) includes "fishing," and a user is in the vicinity of a lake, a virtual beacon can provide the user with a pointer directing the user to a website with information regarding what species of fish abound within that lake, what game fish may be sought there at the particular time of the year corresponding to the user's presence, and the like.

Detail Description Paragraph:

[0150] FIG. 10B depicts an exemplary fairground with four associated virtual beacons 1011, 1012, 1013, and 1014. Virtual beacon 1011, associated with the point in space corresponding to the fair ground's entrance (e.g., gate), is visible to all enabled client devices if its Lat/Lon tags (e.g., the Lat/Lon of the gate) fall within the client's search window, as described above in Section I, and the fair is open. The URL associated with virtual beacon 1011 can be a webpage with general information pertinent to the fair.

Detail Description Paragraph:

[0151] Virtual beacon 1012, associated with a point in space corresponding to an attraction within the fairgrounds, is visible to an enabled client device only if its Lat/Lon tags fall within the client's search window, as described above in Section I, and the fair is open, and the client device is currently within the Lat/Lon boundaries of the fairground. This combination of requisites for receivability imply sequence: the client has entered the fairgrounds. The URL associated with virtual beacon 1012 can be a webpage with more particular information pertinent, e.g. to a specific fair attraction or event or group of attractions and events.

Detail Description Paragraph:

[0152] Virtual beacon 1013, associated with a point in space corresponding to a show at a venue within the fairgrounds, is visible to an enabled client device only if its Lat/Lon tags fall within the client's search window, as described above in Section I, and the fair is open, and the client device is currently within the Lat/Lon boundaries of the fairground, and the client has purchased a ticket for the show at the gate (e.g., or prior to arrival). This combination of requisites for receivability implies a more complex sequence than the last example: the client has purchased a ticket, evinced by a cookie or credential placed upon their device (e.g., cookie 839, credential 835, device 820; FIG. 8), and then entered the fairgrounds. The URL associated with virtual beacon 1013 can be a webpage with information pertinent, e.g., to the show and the performers therein.

Detail Description Paragraph:

[0153] Virtual beacon 1014, associated with a point in space corresponding to an attraction within the fairgrounds, is visible to an enabled client device only if its Lat/Lon tags fall within the client's search window, as described above in Section I, and the fair is open, and the client device is currently within the Lat/Lon boundaries of the fairground, and the user thereof has earned an electronic coupon after having spent a certain requisite amount on clothing. The URL associated with virtual beacon 1014 can be a webpage with information pertinent to special sales on clothing. In the present implementation, Lat/Lon tags are used to exemplify one possible technique for positional tagging. This is not meant to be limiting however. Embodiments of the present invention are well suited to using other positional information. For instance, in one embodiment, altitude tags are included, as well. Tagging can also be implemented based on relative or other positioning.

Detail Description Paragraph:

[0154] FIG. 10C depicts the useful application of virtual beacons having coverage areas along a stretch of roadway (e.g., association with a geographical location corresponding to various parts of the road). In the present example, an accident has occurred within coverage area 2, and a virtual beacon 1030 is generated corresponding to that location and providing information that the accident has

occurred, which can alert an emergency response entity.

Detail Description Paragraph:

[0155] Traffic such as car G within coverage area 2 receive a virtual beacon 1031 that notifies them, e.g., to slow down and expect delays. Traffic in coverage area 1, such as car A receive a virtual beacon 1032 that suggesting an alternate route, such as heading into coverage area 4, instead of into the impacted coverage area 2. Traffic such as car B in coverage area 3 receive a virtual beacon 1033, advising them to exercise caution and not to "rubberneck." The virtual beacons associated with each different location, in this case regions of the roadway, provide client devices within each region with information dynamically pertinent to that particular region. Such dynamic and intelligent flexibility can be based upon programming the individual IAPs to intelligently respond to particular events that occur in associated, in this case near by regions of the roadway, in particular ways, e.g., by providing particularly timely, pertinent, and time-pertinent information. Used in this fashion, virtual beacon 850 can provide safety information as a public service, without the need for police, transport, road, or other agencies having to erect or place a physical beacon in response to varying roadway and other hazards and other conditions.

Detail Description Paragraph:

[0157] In one embodiment, a virtual beacon for selectively providing information relating to a point in three-dimensional space based on context relating to a user of a detector of the virtual beacon. The point in three-dimensional space corresponds to a unique geographical location, such as a latitude and a longitude. The information selectively provided can change dynamically in response to a condition described by the context. This condition relates to the dynamic pertinence of information with respect to the context and the receivability of the virtual beacon by the detector is activated and deactivated in response to the condition. This dynamic pertinence can be based on time or locational aspect of the detector.

Detail Description Paragraph:

[0160] FIG. 11 depicts an exemplary data structure 1100 disposed in a computer memory 1150 for providing information corresponding to a location, according to one embodiment of the present invention. In one embodiment, data structure 1100 functions as a virtual beacon (e.g., virtual beacon 850; FIG. 8B). Data structure 1100 comprises a first data field 1101. Data field 1101 functions to identify a location. Data structure 800 also comprises a second data field 1102. Data field 1102 comprises information corresponding to the location. In one embodiment, data field 1101 comprises a latitude and a longitude. In one embodiment, data field 1102 can a uniform resource locator, a telephone number, an address, or other information.

Detail Description Paragraph:

[0161] The information can also comprise a telephone number, address, or other information. For example, where a party of three was to meet at a certain location and two of them meet prior to the arrival of the third, they may depart and leave the third person a telephone number of one of the other two, so that the third person can contact them. Or the address of a destination and/or a time of arrival, etc., can be left. The telephone number, address, etc., can be left on the field 1102 of a data structure 1100 corresponding to the location of the meeting point. The third person can detect the data structure, which can function as a virtual beacon, upon arrival within the vicinity or proximity of the location.

Detail Description Paragraph:

[0171] In one embodiment, the receivability of the data structure to said client device is activated and deactivated in response to the condition. For instance, before the condition makes the information pertinent with respect to the context, the data structure is not sent. The condition can comprise a quality such as time,

a locational aspect of said client device, or another condition. The locational aspect can comprise a state such as the directional orientation, tilt orientation, residing within a specified area of coverage, motion through a specified area of coverage, accessibility of the location to a position of the client device, or some other locationally relevant state of or relating to the client device. The condition can comprise a sequence of events occurring. In one embodiment, the area of coverage changes dynamically in response to the sequence of events. The processing for displaying downloaded virtual beacons can be done locally (e.g., at device 820; FIG. 8B) to help ensure privacy for users.

Detail Description Paragraph:

[0172] As previously described herein, in some cases a set of virtual beacons are loaded onto a database of a device. For example, in FIG. 8A, the local database 841 contains contextual information. The contextual information may be downloaded from the virtual beacon server 803. The filter 825R accesses context information 830R from the local database 841 based on context 826 (e.g., location, time, direction).

Detail Description Paragraph:

[0173] As an example of a motivation to prevent the unauthorized release of the contextual information 830R from the local database 841 consider the following example. A company may wish to develop an advertisement campaign based on an enigma game. The win the game, a player must solve a sequence of puzzles or questions. In this example game, the answer to each question/puzzle is a location. The user receives the next question upon reaching the location. The winner is the player who reaches the final destination first. The game can be set up by having players download all virtual beacons for the entire game to their mobile device. By downloading all of the virtual beacons at once, a player's privacy is protected in that a back-end server does not know the player's location. That is, if the next virtual beacon were only downloaded when the player was at the location that is the answer to the previous question in the enigma game, then the player's location could be tracked.

Detail Description Paragraph:

[0174] Thus, downloading all of the virtual beacons for the game helps to protect the player's privacy. If the players are honest, the enigma game can unfold fairly. However, it is possible that a player might hack into the database on their device to reveal all the virtual beacons without actually solving the questions to the enigma game. Embodiments of the present invention provide a security measure to reduce or eliminate such unauthorized access to contextual information (e.g., virtual beacons) stored in a local database. These embodiments have applications other than the exemplary game.

Detail Description Paragraph:

[0175] FIG. 13 describes a system 1300 for securely providing information corresponding to a context, according to an embodiment of the present invention. The system in FIG. 13 comprises a backend or virtual beacon server 1303 and a mobile device 1305a having a trusted computing platform 1310a. The backend server 1303 can be implemented in a similar manner as virtual beacon server 60 depicted in FIG. 5 and described herein or the virtual beacon server 803 depicted in FIG. 8A and described herein. However, the backend server 1303 of the present embodiment is not limited to these implementations.

Detail Description Paragraph:

[0176] The mobile computing device 1305a comprises a trusted computing platform 1310a, which in this embodiment has a secure virtual beacon database 1341a and a trusted platform filter 1325a. The mobile device 1305a downloads secure virtual beacons from the backend server 1303 using a session key after authenticating with the backend server 1303. The secure virtual beacons are stored in the secure virtual beacon database 1341a on the trusted platform 1310a and are only accessible

if the proper context is presented to the trusted platform filter 1325a on the trusted platform 1310a. That is, a context is associated with each virtual beacon. For example, the context may be a given location and time. Both the location and time may have a range in values.

Detail Description Paragraph:

[0178] The context logic 1330 is coupled to the trusted platform filter 1325a, such that the trusted platform filter 1325a may access the context from the context logic 1330. The trusted platform filter 1325a determines what, if any, context information should be released from the secure virtual beacon database 1341a based on the context from the context logic 1330. Thus, the trusted platform filter 1325a accesses the secure virtual beacon database 1341a and transfers a virtual beacon (e.g., context information) to the UI 1320 if the context for the virtual beacon is presented to the trusted platform filter 1325a. For example, if the context for a given virtual beacon is the longitude and latitude of a landmark, then the associated virtual beacon will be accessed and displayed on the UI if that context is presented to the trusted platform filter 1325a.

Detail Description Paragraph:

[0180] The mobile computing device 1305a of FIG. 13 optionally comprises a non-secure virtual beacon database 1360 that stores non-secure virtual beacons. The mobile computing device 1305a optionally includes a non-secure filter 1365 associated with the non-secure virtual beacon database 1360. The mobile computing device 1305a may have more data storage available on the mobile computing device 1305a than is available on the trusted platform 1310a, so providing for a second database for virtual beacons may allow for more virtual beacon storage. Further, the computing power of the mobile computing device 1305a may be greater than the computing power of the trusted computing platform 1310a so processing some of the virtual beacons externally from the trusted platform 1310a may allow for improved performance. However, this embodiment of the present invention is very secure. The processing and display of virtual beacons stored in the non-secure virtual beacon database 1360 may be similar to embodiments discussed herein. For example the processing and display of virtual beacons stored in the non-secure virtual beacon database 1360 may be similar to the embodiment depicted in FIG. 8A.

Detail Description Paragraph:

[0181] FIG. 14 is a flowchart of a process 1400 for securely providing information corresponding to a context, according to an embodiment of the present invention. Steps of process 1400 may be stored as instructions on a computer readable medium and executed on a processor. Steps of process 1400 are executed by the trusted platform 1310a of FIG. 13 in one implementation. However process 1400 is not limited to being executed by the trusted platform 1310a of FIG. 13. In step 1410, context that is external to a device is accessed and stored on a trusted computing platform. For example, a mobile device establishes a connection to back-end server, authenticates itself, and establishes a session. Using an obtained session key, virtual beacons are downloaded to the device. The downloaded information may also comprise context associated with each virtual beacon.

Detail Description Paragraph:

[0184] In step 1450, portions of the information that were accessed from the databases in step 1440 are exported from the trusted platform. In this implementation, the exported information includes context information. For example, a virtual beacon is exported.

Detail Description Paragraph:

[0187] In the embodiment of FIG. 15, the mobile computing device 1305b has a secure database 1561 external to the trusted platform 1310b that is used to store encrypted secure context information. Thus, a portion of the data stored in connection with the secure virtual beacons is stored external to the trusted platform 1310b. The mobile computing device 1305b also has a decryption engine 1526

external to the trusted computing platform 1310b. Thus, additional computing duties are performed external to the trusted platform 1310b, as compared to the embodiment of FIG. 13.

Detail Description Paragraph:

[0188] The trusted computing platform 1310b, in this embodiment, has a secure database 1341b that is used to store remaining portions of the data associated with the secure virtual beacons that is not stored external to the trusted platform 1310b.

Detail Description Paragraph:

[0189] In the embodiment depicted in FIG. 15, the mobile device 1305b downloads information from the backend or virtual beacon server 1303 in two stages. The mobile device 1305b establishes a connection to the back-end server 1303, authenticates itself and downloads information into the secure virtual beacon database 1341b on the trusted platform 1310b. This information may include, for each virtual beacon: an identifier, context information, and an encryption key. This information is stored in the clear, in this embodiment. However, this information may be encrypted, if desired.

Detail Description Paragraph:

[0190] The second stage of the download from the back-end server 1303 is to the (encrypted) secure database 1561 external to the trusted computing platform 1310b. This information stored in encrypted secure database 1561 may include, for each virtual beacon: an identifier, a label, a URL, and other information that is pertinent to virtual beacon. Most of this information is encrypted. However, the identifier is stored in the clear in this implementation.

Detail Description Paragraph:

[0191] The trusted computing platform 1310b has a trusted platform filter 1325b that receives context awareness data (e.g., time, location, etc.) from the context logic 1330, which the trusted platform filter 1325b uses to determine which, if any, information should be retrieved from the secure database 1341b on the trusted platform 1310b and exported to the decryption engine 1526. The context entry in the secure database 1341b may be used to determine what information should be released. In this implementation, the information that the trusted platform filter 1325b retrieves from the secure virtual beacon database 1341b include a virtual beacon identifier and its encryption key. This information is passed on to the decryption engine 1526.

Detail Description Paragraph:

[0192] The decryption engine 1526 uses the virtual beacon identifier to locate the appropriate entry in the encrypted secure database 1561. As previously discussed the virtual beacon identifier that is stored in the encrypted secure database 1561 may in fact not be encrypted so as to facilitate the database search for it. Using the encryption key, the decryption engine 1526 decrypts the context information for the appropriate entry in the encrypted secure database 1561 and transfers the decrypted information on to the user interface (UI) 1320. For example, a virtual beacon that was encrypted in the encrypted secure database 1561 is decrypted and forwarded to the UI 1320.

Detail Description Paragraph:

[0193] Thus, the secure virtual beacons are stored in the encrypted secure database 1561 and are only accessible if the proper context is presented to the trusted platform filter 1325b. However, the trusted platform filter 1325b does not, in this embodiment, directly access the virtual beacons, as a decryption engine 1526 external to the trusted platform 1310b performs that computing duty.

Detail Description Paragraph:

[0195] In the embodiment depicted in FIG. 17, the mobile device 1305c downloads

information from the backend or virtual beacon server 1303 in two stages in a similar fashion to the embodiment depicted in FIG. 15. The trusted computing platform 1310c has a trusted platform filter 1325c that receives context awareness data from the context logic 1330, which the trusted platform filter 1325c uses to determine which, if any, information should be retrieved from the secure database 1341c on the trusted platform 1310c. In this implementation, the information that the trusted platform filter 1325c retrieves from the secure virtual beacon database 1341c includes a virtual beacon identifier and its encryption key. This information is passed on to the decryption engine 1726. In the embodiment of FIG. 17, the trusted platform filter 1325c does not export information external to the trusted platform. Rather, the information output by the trusted platform filter 1325c stays on the trusted computing platform 1310c.

Detail Description Paragraph:

[0196] The decryption engine 1726 on the trusted platform 1310c uses the virtual beacon identifier to locate the appropriate entry in the encrypted secure database 1761. Using the encryption key, the decryption engine 1726 decrypts the context information for the appropriate entry in the encrypted secure database 1761 and transfers the decrypted information on to the UI 1320. For example, a virtual beacon that was encrypted in the encrypted secure database 1761 is decrypted and forwarded to the UI 1320. Thus, the decryption keys never leave the trusted computing platform 1310c.

Detail Description Paragraph:

[0197] FIG. 16 is a flowchart of a process for securely providing information corresponding to a context, according to an embodiment of the present invention. Steps of process 1600 may be stored as instructions on a computer readable medium and executed on a processor. Steps of process 1600 are executed by the trusted platform 1310b and decryption engine 1526 of FIG. 15 in one implementation. Steps of process 1600 are executed by the trusted platform 1310c of FIG. 17 in another implementation. However process 1600 is not so limited. In step 1610, a first part of context information that is external to a device is accessed and stored on a trusted computing platform. For example, a mobile device establishes a connection to back-end server, authenticates itself, and establishes a session. Using an obtained session key, the following is downloaded for each virtual beacon: an identifier, context information, and an encryption key.

Detail Description Paragraph:

[0198] In step 1620, a second part of context information that is external to a device is accessed and stored on a secure databases external to the trusted computing platform. The second part of the information may include, for each virtual beacon: an identifier, a label, a URL, and other information that is pertinent to virtual beacon. Typically, the identifier is not stored in encrypted form. The rest of the second part of information is both downloaded and stored encrypted.

Detail Description Paragraph:

[0200] In step 1640, a portion of the information stored on the trusted secure database is accessed based on the context that was accessed in step 1630. The accessing may be performed by a filter, such as filter 1325b in FIG. 15 or filter 1325c in FIG. 17. The information accessed from the secure virtual beacon database may include a virtual beacon identifier and its encryption key.

Detail Description Paragraph:

[0202] In step 1660, the decryption engine uses the virtual beacon identifier to determine which entry in the secure databases external to the trusted computing platform described in step 1620 is relevant. The decryption engine uses the encryption key to decrypt various information associated with that entry.

Detail Description Paragraph:

[0203] In step 1670, the decryption engine forwards the decrypted information on to a user interface for display. For example, a virtual beacon is forwarded to and displayed. Thus, if the proper context information was provided to the filter on the trusted platform, the decryption engine will decrypt the information associated with the context and forward it to the display. The process 1600 then ends.
